

## Quiz 2

22C:80 Programming for Informatics

Monday, April 6th, 2009

**Notes:** The quiz is worth **6 points total**. To get partial credit you must show your work.

---

1. Consider the following function:

```
def test(n):
    sum = 1
    while(sum <= n):
        for i in range(0, n):
            printNow("hello")
        sum = sum*2
```

- (a) How many times will Hello be printed when you call the function `test(4)`?
- (b) How many times will Hello be printed when you call the function `test(n)`? Your answer should be expressed as a function of  $n$ .
- (c) Justify your answer in part (b) with a 1-2 sentence explanation.

2. The code for the functions `partition` and `recursiveQuickSort` are given below:

```
def partition(C, left, right):
    p = left
    for i in range(p+1, right+1):
        if(C[i] < C[p]):
            swap(C, i, p+1)
            swap(C, p, p+1)
            p = p + 1

    return p
```

```
def recursiveQuickSort(C, left, right):
    if(left < right):
        p = partition(C, left, right)
        recursiveQuickSort(C, left, p-1)
        recursiveQuickSort(C, p+1, right)
```

(a) Suppose `C` is the list `[6, 3, 7, 1, 9, 2, 7, 6]` and you call `partition(C, 1, 5)`. How does `C` change as a result of this call? What is the value returned by `partition(C, 1, 5)`?

(b) Suppose that we inserted a “print statement” that prints (in one line) `C`, `left`, and `right`, just before the call to the `partition` function in `recursiveQuickSort`. What are the first three lines of output you will see when you call `recursiveQuickSort(C, 0, 7)`, with `C` being the list `[6, 3, 7, 1, 9, 2, 7, 6]`.

3. Consider the variant of *job scheduling* problem in which you get paid by the hour for usage of your conference room. So, your goal would be to maximize, not the number of requests you accept, but the total amount of time for which your conference room gets used.
- (a) Given this new goal, the “ends first” greedy algorithm that repeatedly picks an available request with leftmost right endpoint is no longer optimal. That is, there is a collection of requests for which there is a schedule that yields more revenue to you than what you would get by using the schedule produced by the “ends first” algorithm. Show such a collection of requests, clearly showing what the “ends first” algorithm would produce and how it is possible to do better.
- (b) Devise an alternate greedy algorithm for this version of the job scheduling problem, that seems more reasonable to you. Describe it clearly in plain English or in pseudocode. You do not have to say anything about its correctness.
