CS:5810
Formal Methods in Software Engineering

Introduction to Alloy
Part 2

Copyright 2001-15, Matt Dwyer, John Hatcliff, Rod Howell, Laurence Pilard, and Cesare Tinelli. Created by Cesare Tinelli and Laurence Pilard at the University of Iowa from notes originally developed by Matt Dwyer, John Hatcliff, Rod Howell at Kansas State University. These notes are copyrighted materials and may not be used in other course settings outside of the University of Iowa in their current form or modified form without the express written permission of one of the copyright holders. During this course, students are prohibited from selling notes to or being paid for taking notes by any person or commercial firm without the express written permission of one of the copyright holders.
Alloys Constraints

- Signatures and fields define classes (of atoms) and relations between them
- Alloy models can be refined further by adding *formulas* that express additional constraints over those sets and relations
- Several operators are available to express both logical and relational constraints
Logical Operators

The usual logical operators are available, often in two forms:

- **not**: `!` (Boolean) negation
- **and**: `&&` conjunction
- **or**: `||` disjunction
- **implies**: `=>` implication
- **else**: `<>` alternative
- **equivalence**
Quantifiers

Alloy includes a rich collection of quantifiers

- all x: S | F  F holds for every x in S
- some x: S | F  F holds for some x in S
- no x: S | F  F holds for no x in S
- lone x: S | F  F holds for at most 1 x in S
- one x: S | F  F holds for exactly 1 x in S
Predefined Sets in Alloy

There are three predefined set constants:

- **none**: empty set
- **univ**: universal set
- **ident**: identity

Example. For a model instance with just the two sets:

Man = \{(M0),(M1),(M2)\}
Woman = \{(W0),(W1)\}

the constants have the values

none = {}
univ = \{(M0),(M1),(M2),(W0),(W1)\}
ident =\{(M0,M0),(M1,M1),(M2,M2),(W0,W0),(W1,W1)\}
Everything is a Set in Alloy

• There are no scalars
  – We never speak directly about elements (or tuples) of relations
  – Instead, we can use singleton relations:

    one sig Matt extends Person

• Quantified variables always denote singleton relations:

  all x : S | ... x ... 
  x = \{t\} for some element t of S
Set Operators

+ union
& intersection
- difference
in subset
= equality
!= disequality

• Ex: Married men, 
  
  Married & Man
Relational Operators

- \(\rightarrow\) arrow (product)
- \(\sim\) transpose
- \(\cdot\) dot join
- \([-]\) box join
- \(\wedge\) transitive closure
- \(*\) reflexive-transitive closure
- \(<::\) domain restriction
- \(::>\) image restriction
- \(++\) override
Arrow Product

\[ p \rightarrow q \]

- \( p \) and \( q \) are two relations
- \( p \rightarrow q \) is the relation you get by taking every combination of a tuple from \( p \) and a tuple from \( q \) and concatenating them.

Examples:

Name = \{ (N0), (N1) \}
Addr = \{ (D0), (D1) \}
Book = \{ (B0) \}

Name -> Addr = \{ (N0,D0), (N0,D1), (N1,D0), (N1,D1) \}
Book -> Name -> Addr =
\{ (B0,N0,D0), (B0,N0,D1), (B0,N1,D0), (B0,N1,D1) \}
Transpose

\sim p

- take the mirror image of the relation \( p \),
  i.e. reverse the order of atoms in each tuple.

Example:

- \text{example} = \{(a_0, a_1, a_2, a_3), (b_0, b_1, b_2, b_3)\}
- \sim\text{example} = \{(a_3, a_2, a_1, a_0), (b_3, b_2, b_1, b_0)\}

How would you use \( \sim \) to express the parents relation?

\sim\text{children}
Relational Composition (Join)

\[ p.q \]

- \( p \) and \( q \) are two relations that are not both unary
- \( p.q \) is the relation you get by taking every combination of a tuple from \( p \) and a tuple from \( q \) and adding their join, if it exists.
How to join tuples?

• What is the join of theses two tuples?
  – \((a_1, \ldots, a_m)\)
  – \((b_1, \ldots, b_n)\)

If \(a_m \neq b_1\) then the join is undefined
If \(a_m = b_1\) then it is: \((a_1, \ldots, a_{m-1}, b_2, \ldots, b_n)\)

• Examples:
  – \((a, b) \cdot (a, c, d)\) undefined
  – \((a, b) \cdot (b, c, d) = (a, c, d)\)

• What about \((a) \cdot (a)\) ? Not defined!

\(t_1 \cdot t_2\) is not defined if \(t_1\) and \(t_2\) are both unary tuples.
Exercises

• What’s the result of these join applications?

- \{ (a, b) \} \cdot \{ (c) \}
- \{ (a) \} \cdot \{ (a, b) \}
- \{ (a, b) \} \cdot \{ (b) \}
- \{ (a) \} \cdot \{ (a, b, c) \}
- \{ (a, b, c) \} \cdot \{ (c), (c, d), (b, c) \}
- \{ (a, b) \} \cdot \{ (a, b, c) \}
- \{ (a, b, c, d) \} \cdot \{ (d, e, f), (d, a) \}
- \{ (a) \} \cdot \{ (b) \}
Examples:

to maps a message to the name it should be sent to

address maps names to addresses

- to = {(M0, N0), (M0, N2), (M1, N2), (M2, N3)}
- address = {(N0, D0), (N0, D1), (N1, D1), (N2, D3)}

to.address maps a message to the addresses it should be sent to

- to.address = {(M0, D0), (M0, D1), (M0, D3), (M1, D3)}
Exercises

• Given a relation \texttt{addr} of arity 4 that contains the tuple \texttt{b->n->a->t} when book \texttt{b} maps name \texttt{n} to address \texttt{a} at time \texttt{t}, and given a specific book \texttt{B} and a time \texttt{T}:

  \begin{itemize}
    \item \texttt{addr} = \{(B0, N0, D0, T0), (B0, N0, D1, T1), (B0, N1, D2, T0), (B0, N1, D2, T1), (B1, N2, D3, T0), (B1, N2, D4, T1)\}
    \item \texttt{T} = \{(T1)\} \quad \texttt{B} = \{(B0)\}
  \end{itemize}

The expression \texttt{B.addr.T} is the name-address mapping of book \texttt{B} at time \texttt{T}. What is the value of \texttt{B.addr.T}?

• When \texttt{p} is a binary relation and \texttt{q} is a ternary relation, what is the arity of the relation \texttt{p.q}?

• Join is not associative, why?
  (i.e., \texttt{(p.q).r} and \texttt{p.(q.r)} are not always equivalent)
Example: Family Structure

• How would you use join to find Matt’s children or grandchildren?
  – `matt.children`  // Matt’s children
  – `matt.children.children`  // Matt’s grandchildren

• What if we want to find Matt’s descendants?
Box Join

$p[q]\$

– Semantically identical to dot join, but takes its arguments in different order

\[ p[q] \equiv q.p \]

Example: Matt’s children or grandchildren?

– `children[matt]` // Matt’s children
– `children.children[matt]` // Matt’s grandchildren
– `children[children[matt]]` // Matt’s grandchildren
Transitive Closure

\( \Box r \)

- Intuitively, the transitive closure of a relation \( r : S \times S \) is what you get when you keep navigating through \( r \) until you can’t go any farther.

\[ \Box r = r + r \cdot r + r \cdot r \cdot r + \ldots \]
Example: Family Structure

• What if we want to find Matt’s ancestors or descendants?
  
  – m att.\^\text{children} \quad // \text{Matt’s descendants}
  
  – m att.\^\text{~children} \quad // \text{Matt’s ancestors}

• How would you express the constraint “\text{No person can be their own ancestor}”

  \text{no } p : \text{Person} \mid p \text{ in } p.\^\text{~children}
Reflexive-transitive closure

\[ *r = \^r + \text{iden} \]

\[ (S0,S1) \]
\[ (S1,S2) \]
\[ (S2,S3) \]
\[ (S4,S7) \]
\[ r \]

\[ (S0,S0) \]
\[ (S1,S1) \]
\[ (S2,S2) \]
\[ (S3,S3) \]
\[ (S4,S4) \]
\[ (S7,S7) \]

\[ \^r \]

\[ *r \]

\[ \text{iden} \]
Domain and Image Restrictions

• The restriction operators are used to filter relations to a given domain or image

• If S is a set and r is a relation then
  – $s \prec r$ contains tuples of r starting with an element in $S$
  – $r \succ s$ contains tuples of r ending with an element in $S$

• Example:
  – Man = {(M0),(M1),(M2),(M3)}
  – Woman = {(W0),(W1)}
  – children = {(M0,M1),(M0,M2),(M3,W0),(W1,M1)}
  – Man $\prec$ children = {(M0,M1),(M0,M2),(M3,W0)}
    // father-child
  – children $\succ$ Man = {(M0,M1),(M0,M2),(W1,M1)}
    // parent-son
Override

\( p \; ++ \; q \)
- \( p \) and \( q \) are two relations of \textit{arity two or more}
- the result is like the union between \( p \) and \( q \) except that tuples of \( q \) can replace tuples of \( p \); any tuple in \( p \) that matches a tuple in \( q \) starting with the same element is dropped
- \( p \; ++ \; q = p - (\text{domain}(q) \; <: \; p) + q \)

Example
- \( \text{oldAddr} = \{(N0,D0),(N1,D1),(N1,D2)\} \)
- \( \text{newAddr} = \{(N1,D4),(N3,D3)\} \)
- \( \text{oldAddr} \; ++ \; \text{newAddr} = \{(N0,D0),(N1,D4),(N3,D3)\} \)
Operator Precedence

||
<=>
=>
& &
!
=
!=
in
+
-
++
&
->
<:
::
>
[]
.
~
* ^
Example: Family Structure

How would you express the constraint “No person can have more than one father and mother”?
Example: Family Structure

How would you express the constraint “No person can have more than one father and mother”? 

\[
\text{all p: Person | (lone (children.p & Man)) and (lone (children.p & Woman))}
\]

Equivalently:

\[
\text{all p: Person | (lone (Man <: children).p) and (lone (Woman <: children).p)}
\]

This is an example of a negative constraint that is easier to state positively (to make use of the lone operator)
Set Comprehension

\[
\{ x : S \mid F \}
\]

– the set of values drawn from set \( S \) for which \( F \) holds

How would use the comprehension notation to specify the set of people that have the same parents as Matt?

(assuming \texttt{Person} has a \texttt{parents} field)
Set Comprehension

\{ \mathbf{x} : S \mid F \} 

– the set of values drawn from set \( S \) for which \( F \) holds

How would use the comprehension notation to specify the set of people that have the same parents as Matt?

\{ \texttt{q: Person } \mid \texttt{q.parents = matt.parents} \} 

(assuming Person has a parents field)
Example: Family Structure

How would you express the constraint “A person P’s siblings are those people, other than P, with the same parents as P”
Example: Family Structure

How would you express the constraint “A person $P$’s siblings are those people, other than $P$, with the same parents as $P$”

\[
\text{all } p: \text{Person} \mid \quad p.\text{siblings} = \quad \{ q: \text{Person} \mid p.\text{parents} = q.\text{parents} \} - p
\]
Example: Family Structure

Every married man (woman) has a wife (husband)

A spouse can’t be a sibling
Example: Family Structure

*Every married man (woman) has a wife (husband)*

\[
\text{all } p: \text{Married} \mid \\
(p \text{ in Man } \Rightarrow p.\text{spouse in Woman}) \text{ and } \\
(p \text{ in Woman } \Rightarrow p.\text{spouse in Man})
\]

*A spouse can’t be a sibling*

\[
\text{no } p: \text{Married} \mid \\
p.\text{spouse in p.siblings}
\]
Let

You can factor expressions out:

\[
\text{let } x = e \mid A
\]

– Each occurrence of the variable \( x \) will be replaced by the expression \( e \) in \( A \)

Example: *Each married man (woman) has a wife (husband)*

\[
\text{all } p : \text{Married} \mid
\text{let } q = p.\text{spouse} \mid
(p \text{ in } \text{Man} \Rightarrow q \text{ in } \text{Woman}) \text{ and }
(p \text{ in } \text{Woman} \Rightarrow q \text{ in } \text{Man})
\]
Facts

• Additional constraints on signatures and fields are expressed in Alloy as **facts**

```alloy
fact Name {
  F1
  F2
  ...
}
```

• AA looks for instances of a model that also satisfy **all** of its fact constraints
Example Facts

Family Structure:

-- No person can be their own ancestor

-- At most one father and mother

-- a person's siblings are other persons with the same parents
Example Facts

Family Structure:

-- No person can be their own ancestor
\texttt{fact selfAncestor \{ \\
  no p: Person | p in p.^parents \\
\}}

-- At most one father and mother
\texttt{fact loneParents \{ \\
  all p: Person | lone (p.parents & Man) and \\
    lone (p.parents & Woman) \\
\}}

-- a persons's siblings are other persons with the same parents
\texttt{fact siblingsDefinition \{ \\
  all p: Person | \\
    p.siblings = \{ q: Person | p.parents = q.parents \} - p \\
\}}
Example Facts

*Family Structure:*

```plaintext
fact social {
    -- Every married man (woman) has a wife (husband)

    -- A spouse can't be a sibling

    -- A person can't be married to a blood relative
}
```
Example Facts

Family Structure:

\textbf{fact} social \{ \\
\hspace{1em} -- Every married man (woman) has a wife (husband) \\
\hspace{1em} all p: Married | \\
\hspace{2em} let s = p.spouse | \\
\hspace{3em} (p in Man => s in Woman) and \\
\hspace{3em} (p in Woman => s in Man) \\
\hspace{1em} -- A spouse can't be a sibling \\
\hspace{1em} no p: Married | p.spouse in p.siblings \\
\hspace{1em} -- A person can't be married to a blood relative \\
\hspace{1em} no p: Married | \\
\hspace{2em} some (p.*parents & (p.spouse).*parents) \\
\}

Run Command

• Used to ask AA to generate an instance of the model

• May include *conditions*
  – Used to guide AA to pick model instances with certain characteristics
  – E.g., force certain *sets and relations* to be non-empty
  – In this case, not part of the “true” specification
Run Command

• To analyze a model, you add a run command and instruct AA to execute it.
  – the run command
tells the tool to search for an instance of the model
  – you may also give a scope to signatures
    bounds the size of instances that will be considered

• AA executes only the first run command in a file
Scope

• **Limits the size of instances** considered to make instance finding feasible

• Represents the maximum number of tuples in each **top-level signature**

• **Default value** = 3
Run Conditions

• We can use condition schemas to encode realism constraints to e.g.,
  – Force generated models to include at least one married person, or one married man, etc.

• Condition schemas can be used to implement constraint macros
  – This allows common constraints to be shared
Run Example

**Family Structure:**

-- The simplest run command
-- The scope of every signature is 3
run {}

-- The scope scope of every signature is 5
run {} for 5

-- With conditions, forcing each set to be populated
-- Set the scope to 2
run {some Man && some Woman && some Married} for 2

-- Other scenarios
run {some Woman && no Man} for 7
run {some Man && some Married && no Woman}
Exercises

• Load family-2.als
• Execute it
• Analyze the metamodel
• Look at the generated instance
• Does it look correct?
• What if anything would you change about it?
Empty Signatures

• The analyzer’s algorithms prefer smaller instances
  – Often it produces empty signatures or otherwise trivial instances
  – It is useful to know that these instances satisfy the constraints (since you may not want them)
• Usually, they do not illustrate the interesting behaviors that are possible
Exercises

• Load family-3.als
• Execute it
• Look at the generated instance
• Does it look correct?
• How can you produce
  – two married couples?
  – a non empty married relation and a non-empty siblings relation?
Assertions

- Often we believe that our model *entails* certain *constraints* that are not directly expressed
  - e.g., *some A & (A in B)* entails *some B*

- We can define these additional constraints as *assertions* and use the analyzer to check if they hold
  - e.g., *assert myAssertion { some B }*
    *check myAssertion*
Assertions

• If the constraint in an assertion does not hold, the analyzer will produce a counterexample instance.

• If you expect the constraint to hold but it does not, you can either
  – make it into a fact, or
  – refine your model until the assertion holds.
Assertions

• No person has a parent that is also a sibling

  assert a1 { all p: Person | no p.parents & p.siblings }

• A person’s siblings are his/her siblings’ siblings

  assert a2 { all p: Person | p.siblings = p.siblings.siblings }

• No person shares a common ancestor with his/her spouse (i.e., spouse isn’t related by blood)

  assert a3 { no p: Married | some (p.^parents & p.spouse.^parents) }
Assertion Scopes

• You can specify a scope explicitly for any signature, but:

  – If a signature has been given a bound

  – Then the bound of its supersignature or any other extension of the same supersignature can be determined
Example Scope

```java
abstract sig Object {}
sig Directory extends Object {}
sig File extend Object {}
sig Alias extend File {}
```

We consider an assertion \( A \).

- **well-formed:**
  - check \( A \) for 5 Object
  - check \( A \) for 4 Directory, 3 File
  - check \( A \) for 5 Object, 3 Directory
  - check \( A \) for 3 Directory, 3 Alias, 5 File

- **ill-formed** because it leaves the bound of \( \text{File} \) unspecified
  - check \( A \) for 3 Directory, 3 Alias
Example Scope

```plaintext
abstract sig Object {}

sig Directory extends Object {}

sig File extends Object {}

sig Alias extends File {}

• check A for 5 [or] run {} for 5 places a bound of 5 on each top-level signature (in this case just Object)

• check A for 5 but 3 Directory additionally places a bound of 3 on Directory, and a bound of 2 on File by implication

• check A for exactly 3 Directory, exactly 3 Alias, 5 File
   limits File to at most 5 tuples, but requires that Directory and Alias have exactly 3 tuples each
```
Size Determination

Size determined in a signature declaration has priority on size determined in scope

Example:

```
abstract sig Color {}
one sig red, yellow, green extends color {}
sig Pixel {color: one Color}
```

```
check A for 2
```

limits the signature `Pixel` to 2 elements, but assigns a size of exactly 3 to `Color`
Exercises

• Load family-4.als
• Execute it
• Look at the generated counter-examples
• Why is SiblingsSibling false?
• Why is NoIncest false?
Problems with Assertions

Analyzing SiblingSiblings ...

Scopes: Person(3)

Counterexample found:

Person = {M, W0, W1}
Man = {M}
Woman = {W0, W1}
Married = {M, W1}

children = {(W0, W1)}
siblings = {((M, W0), (W0, M))}
spouse = {((M, W1), (W1, M))}

M.siblings = {W0}
M.siblings.siblings = {M}
Problems with Assertions

Analyzing NoIncest ...
Scopes: Person(3)
Counterexample found:

Person = \{M0,M1,W\}
Man = \{M0,M1\}
Woman = \{W\}
Married = \{M1,W\}

children = \{(M0,W),(W,M1)\}
siblings = {} 
spouse = \{(M1,W),(W,M1)\}

(M0 is an Ancestor of M1 
and 
M0 is an ancestor of W ) 
and 
M1 and W are married
Exercises

• Fix the specification in `family-4.als`
  – If the model is underconstrained, add appropriate constraints
  – If the assertion is not correct, modify it

• Demonstrate that your fixes yield no counterexamples
  – Does varying the scope make a difference?
  – Does this mean that the assertions hold for all models?
Exercises

• Express the notion of “blood relative” (share common ancestor) as a condition parameterized on two singleton sets p and q that holds when p and q have a common ancestor

• Add an extra group of invariants that add common social constraints on the husband/wife and parent relations
  – A person can’t have children with a blood relative
  – A person can’t be married to a blood relative
Functions and Predicates

Parametrized macros for terms and formulas
  – Can be named and reused in different contexts (facts, assertions and conditions of run)
  – Can have zero or more parameters
  – Used to factor out common patterns

Functions are good for:
  – set expressions you want to reuse in different contexts

Predicates are good for:
  – formulas you want to reuse in different contexts
Functions

A named set expression, with zero or more parameters

Examples:

– The parents relation
  ```
  fun parents [] : Person -> Person {\sim \text{children}}
  ```

– The sisters function
  ```
  fun sisters [p: Person] : Woman {
    \{w: Woman | w in p.siblings\}
  }
  ```

– Used in a formula
  ```
  all p: Person | not (p in p.^parents or p in sisters[p])
  ```
Predicates

A named formula, with zero or more parameters

Predicates are not included when analyzing other schemas (e.g., facts or assertions) unless they are applied to actual arguments in the schemas being analyzed

Example:

- Two persons are blood relatives iff they have a common ancestor
  
  ```
  pred BloodRelated [p: Person, q: Person] { 
    some (p.*parents & q.*parents) 
  }
  ```

- A person can't be married to a blood relative
  
  ```
  no p: Married | BloodRelated[p, p.spouse]
  ```
Predicate or Fact?

• Predicates are (parametrized) definitions of constraints

• Facts are assumed constraints

• Note: You can package constraints as predicates and then use those predicates in facts

    pred IsSingle[p: Person] { not (p in Married) }
pred IsFather[p: Man] { some p.children }

    fact { some q: Man | IsSingle[p] & IsFather[q] }
Exercises

• Define a predicate that characterizes the notion of “in-law” for the family example

• Write a fact stating that a person is an in-law of their in-laws

• Add these to the family example and run it through AA

• Can you express this same notion in another way in the Alloy model?
  
  – Do so and run it through AA
  
  – Which approach is better? Why?
Exercises

• Add an assertion stating that a person has no married in-laws

• What is the minimum scope for set Person for which ACA can find a counterexample?

• How would you use ACA to prove that your answer is truly the minimum scope?

• prove it!
Acknowledgements

The family structure example is based on an example by Daniel Jackson distributed with the Alloy Analyzer
